In Dart, **getters and setters** are special methods that let you control how a variable is accessed and modified. They're part of writing clean, safe, and maintainable code—especially when working with classes.

🔹 What are getters and setters?

- **Getter** → a method that *reads* a value
- **Setter** → a method that *updates* a value

They look like normal properties when used, but behind the scenes they're functions.

🔹 Why use them?

You *could* just use public variables, but getters/setters give you:

1. Control over data

You can validate or transform values before storing them.

2. Encapsulation

You hide internal implementation details.

3. Flexibility

You can change logic later without breaking other code.

🔹 Key notes

- _variable → private inside the file
- Getter has **no parameters**
- Setter has **exactly one parameter**
- They make your code safer and cleaner

🔹 When should you use them?

Use getters/setters when:

- You need **validation**
- You want **read-only properties**
- You may change logic later
- You want to protect internal data
